THE TETHYAN BIVALVE ROUDAIRIA FROM THE UPPER CRETACEOUS OF CALIFORNIA

by M. X. KIRBY and L. R. SAUL

ABSTRACT. The Tethyan genus Roudairia is described for the first time from North America. A new species, Roudairia squiresi, occurs in the shallow-marine, basal beds of the San Francisquito Formation (uppermost Maastrichtian) at Warm Springs Mountain, Los Angeles County, California. The earliest representatives of the genus Roudairia are from the Cenomanian of north and west Africa. The genus later migrated westward to the western Tethyan Realm and into California during the latest Cretaceous. The presence of R. squiresi suggests warm water in California at the end of the Cretaceous. The taxonomic status of two closely related genera, Cicatrea and Veniella, in relation to Roudairia, remains unclear. However, among these three related taxa, there are at least two distinct generic groups present. The first is represented by Veniella and the second by Roudairia. Specimens from Africa and Madagascar, previously ascribed to 'Cicatrea' cordialis, belong in the second group. Whether Cicatrea cordialis from India also belongs in this second group cannot be determined until additional specimens provide better morphological data.

SEVERAL specimens of a new species, Roudairia squiresi, were collected from basal beds of the San Francisquito Formation on Warm Springs Mountain, in the San Gabriel Mountains, Los Angeles County, southern California (Text-fig. 1). Turritellid gastropods associated with R. squiresi at Warm Springs Mountain indicate a very late Maastrichtian age for the basal San Francisquito Formation (Saul 1983). The basal San Francisquito Formation at Warm Springs Mountain is part of a shallow-marine phase of a transgressive sequence that continued across the Cretaceous/Tertiary boundary into the Palaeocene (Kooser 1980; Kirby et al. 1991).

A fragment of a left valve that resembles R. squiresi was found in undifferentiated Upper Cretaceous rocks at Dip Creek, south shore of Lake Nacimiento, San Luis Obispo County, central California (Text-fig. 1). Associated Turritellid gastropods and an ammonite indicate a latest Maastrichtian age (Saul 1983).

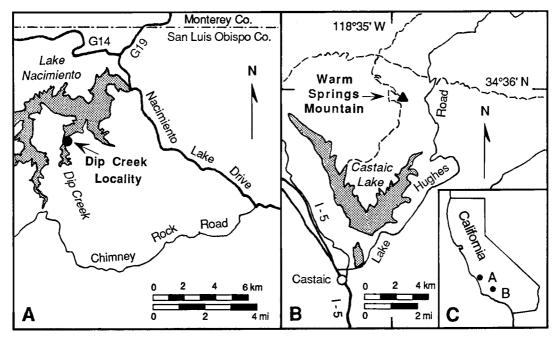

Roudairia has not previously been reported from North America. One species is known from the Upper Cretaceous of Jamaica (Trechmann 1927), and four species are known from the Upper Cretaceous of Peru (Brüggen 1910; Lisson 1925; Olsson 1934, 1944). A closely related genus, Veniella Stoliczka, 1870, is present in Western Interior and Gulf Coast, North American deposits of Turonian to Maastrichtian age. Another closely related taxon, Cicatrea Stoliczka, 1870, is from the Upper Cretaceous of India.

The palaeobiogeographical distributions of *Roudairia*, *Veniella*, and *Cicatrea* are clouded by difficulties in determining their generic and specific characters. Many of the pioneering reports of species assignable to these genera failed to note important morphological features and were vague as to stratigraphical position. Dartevelle and Freneix (1957) considered *Roudairia* and *Cicatrea* to be synonyms of *Veniella*, and therefore placed their species in *Veniella*. They indicated the biogeographical provenance of these species, but did not reassess completely their stratigraphical positions.

A complete review is beyond the scope of this paper, but the work of Dartevelle and Freneix (1957), which delineates characters of four widely occurring species, 'Cyprina (Cicatrea)' cordialis Stoliczka, 1870, 'Trigonia' auressensis Coquand, 1862, Roudairia drui Munier-Chalmas, 1881, and 'Cyprina' forebesiana Stoliczka, 1870, assists in assigning the first three of these species to Roudairia and the fourth to Veniella.

TEXT-FIG. 1. Locality maps showing (A) Dip Creek, (B) Warm Springs Mountain, and (C) California.

This paper describes the stratigraphy and depositional environments associated with *R. squiresi*, discusses the Late Cretaceous palaeobiogeography of the genus *Roudairia*, compares the generic characters of *Veniella* and *Cicatrea* with those of *Roudairia*, and concludes with the description of *R. squiresi*.

STRATIGRAPHY AND DEPOSITIONAL ENVIRONMENTS

The most complete specimens of R. squiresi are from the lowermost San Francisquito Formation at Warm Springs Mountain (Text-fig. 2). The San Francisquito Formation ranges in age from late Maastrichtian to late Palaeocene (Dibblee 1967; Kooser 1980, 1982). At Warm Springs Mountain, the formation was deposited on a granite-gneiss basement that is cut by dykes of early Maastrichtian age (Joseph et al. 1982). The San Francisquito Formation represents a marine-transgressive sequence that consists of shallow-marine deposits grading upsection into deeper submarine-fan deposits (Kooser 1980; Kirby 1991). The lower part of the formation contains a conformable section across the Cretaceous/Tertiary boundary (Kirby et al. 1991), as defined by the Turritella zonation of Saul (1983). Roudairia squiresi was found 5 m below this boundary (Text-fig. 2).

Eight unabraded valves, including one right valve, three left valves, two articulated specimens, and one fragment, were found in a feldspathic sandstone at Warm Springs Mountain (Kirby 1991). The single-valved specimens had probably been transported a short distance, whereas the articulated specimens were most likely in situ. The specimens were associated with the gastropods Turritella webbi Saul, 1983, Turritella chaneyi orienda Saul, 1983, Anchura? sp., and with the bivalves Cucullaea sp. nov., Brachidontes? sp. nov., and Callistalox fragilis (Gabb, 1869). Turritella webbi, Turritella chaneyi orienda, and Brachidontes are characteristic of a shallow-marine environment (Keen 1971; Saul 1983).

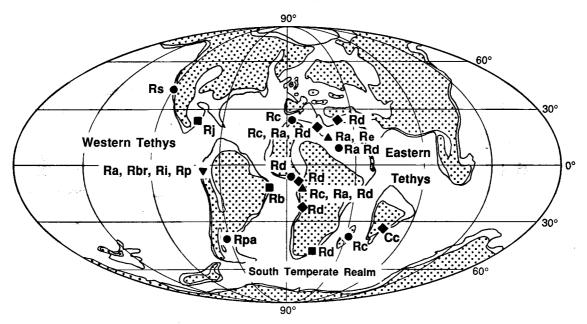

TEXT-FIG. 2. Stratigraphical section of the basal San Francisquito Formation, Warm Springs Mountain, California, showing chronostratigraphy, lithology, depositional environments, and stratigraphical position of *Roudairia squiresi* type locality (LACMIP locality 14312) (after Kirby 1991). Note transgressive nature of stratigraphical section.

Feldspathic sandstone crops out from the base of the San Francisquito Formation to 47 m above the base of the formation (Text-fig. 2). The sandstone is silty, very fine- to medium-grained, and poorly sorted. Although mostly structureless, the sandstone contains indistinct planar bedding locally. Bioturbation is very abundant. Fossiliferous lenses, up to 210 mm thick, are present throughout the feldspathic sandstone. These lenses are inferred to be storm-lag deposits (Kirby 1991).

Abundant bioturbation indicates deposition below fair weather wave base, and storm-lag deposits indicate deposition above storm wave base. Both these features indicate deposition of the feldspathic sandstone in the shallow-marine, transition zone (Kirby 1991).

These transition-zone deposits are part of a shallow-marine, transgressive sequence that grades upsection into offshore deposits. The underlying granite-gneiss basement and an overlying submarine-channel conglomerate stratigraphically bound the sequence (Text-fig. 2). This 110 m thick sequence is between 68.5 Ma and 63.8 Ma in age, based on the *Turritella* zonation of Saul (1983). Deposition of this transgressive sequence probably resulted from both basinal subsidence and eustatic transgression.

TEXT-FIG. 3. Palaeobiogeographical distribution of Cicatrea and Roudairia species on a Maastrichtian palaeogeographic map (Ziegler et al. 1982). Cretaceous palaeobiogeographical names after Kaufmann (1973). Plotted occurrences range from the Cenomanian to the Maastrichtian. Key to species: Cc = Cicatrea cordialis (Stoliczka 1870); Ra = R. auressensis (Coquand 1862) (Dartevelle and Freneix 1957); Rb = R. brasiliensis Maury, 1930; Rbr = R. brüggeni (Lisson 1925) (Olsson 1944); Rc = R. cordialis (Stoliczka 1870) (Douvillé 1904; Boule and Thevenin 1906; Dartevelle and Freneix 1957); Rd = R. drui Munier-Chalmas, 1881 (Rennie 1930; Dartevelle and Freneix 1957); Re = R. elongata Naldini, 1948; Ri = R. intermedia (Brüggen 1910) (Dartevelle and Freneix 1957; Willard 1966); Rj = R. jamaicensis Trechmann, 1927; Rp = R. peruviana Olsson, 1934; Rpa = R. pampaensis Leanza and Hünicken, 1970; Rs = R. squiresi sp. nov. (this paper). Symbols indicate the age of the oldest specimens found at each locality: △ = Cenomanian; ▼ = Turonian; ■ Campanian; ● = Maastrichtian; ◆ = Late Cretaceous.

A fragment of a left valve resembling R. squiresi was found at Dip Creek. This fragment was found associated with turritellid gastropods and other shallow-water molluscs in very coarse-grained, conglomeratic sandstone and conglomerate beds. Grove (1986) interpreted these sandstone and conglomerate beds to be turbidites that were deposited in deep water.

Taliaferro (1944) referred the Dip Creek strata to his 'Dip Creek formation'. But Durham (1968) mapped outcrops along the north shore of Lake Nacimiento as unnamed Upper Cretaceous and Lower Tertiary rocks. Grove (1986) used this designation for the outcrops along the south shore of Lake Nacimiento. Confident assignment of the Dip Creek section to a formation can only be done after detailed geological mapping in the Lake Nacimiento area is undertaken (V. M. Seiders, pers. comm. 1992).

PALAEOBIOGEOGRAPHY

The genus *Roudairia* has a South Temperate to Tethyan distribution (Text-fig. 3. Cretaceous palaeobiogeographical names as defined by Kauffman 1973.) The genus *Veniella*, which as plotted by Dartevelle and Freneix (1957, text-fig. 3) included *Cicatrea* and *Roudairia*, has a South Temperate to North Temperate distribution. Text-figure 4 shows the biogeographical distributions of *Cicatrea*,

Location	California	Peru	WI & GC USA	Jamaica	Argentina	Brazil	N. Africa	W. Africa	S. Africa	Madagascar	India

Turonian		R	V				V	R V	V	V	
Cenomanian							R V	R V			

TEXT-FIG. 4. Location of *Cicatrea* spp. (C), *Roudairia* spp. (R), and *Veniella* spp. (V) through time (based on Stoliczka 1870; Meek 1876; Douvillé 1904; Boule and Thevenin 1906; Trechmann 1927; Maury 1930; Rennie 1930; Olsson 1934, 1944; Naldini 1948; Dartevelle and Freneix 1957; Willard 1966; Leanza and Hünicken 1970). Note that ages are not to scale. WI = Western Interior. GC = Gulf Coast.

Roudairia, and Veniella through time. The earliest record of Roudairia is from the Cenomanian of north and west Africa (Naldini 1948; Dartevelle and Freneix 1957; Cooper 1978). Specimens from these areas range in age from Cenomanian to Maastrichtian. Willard (1966) reported Roudairia from the Turonian of Peru. In the Coniacian, Roudairia is found in Peru and west Africa (Olsson 1934, 1944; Dartevelle and Freneix 1957). In the Campanian, Roudairia is reported from Peru, Jamaica, Brazil, north Africa, west Africa, and south Africa (Trechmann 1927; Maury 1930; Rennie 1930; Olsson 1934, 1944; Dartevelle and Freneix 1957). In the Maastrichtian, Roudairia is reported from California (this paper), Peru, Argentina, north Africa, west Africa, and Madagascar (Douvillé 1904; Olsson 1934, 1944; Dartevelle and Freneix 1957; Leanza and Hünicken 1970).

Abbass (1962) described a new species of *Roudairia* from the Danian of Egypt. If his new species, *Roudairia awadi*, is indeed a *Roudairia*, then *Roudairia* evidently survived the Cretaceous/Tertiary mass extinction and lived on into the Palaeocene. His description and figures of *R. awadi*, however, permit doubt as to whether his specimens actually belong to *Roudairia*.

The palaeobiogeographical distribution of *Roudairia* suggests that the genus evolved either in the northern part of the South Temperate Realm or in the Tethyan Realm before or during the Cenomanian. The genus later migrated westward to the western Tethys during the Late Cretaceous. *Roudairia squiresi*, or one of its antecedents, migrated from Central or South America into California in the Maastrichtian (Text-figs 3–4). The migration of the Tethyan *Roudairia* into the northeastern Pacific at this time suggests the presence of warm water in California at the end of the Cretaceous.

Roudairia squiresi of California is most similar to Roudairia peruviana Olsson, 1934, which is present in the Maastrichtian Monte Grande Formation and undifferentiated rocks of Campanian to Maastrichtian age in northern Peru (Olsson 1934, 1944). Roudairia peruviana is older than R. squiresi. Roudairia jamaicensis Trechmann, 1927, from the Campanian of Jamaica (Trechmann 1927), is less similar to, and is also older than R. squiresi. The present findings extend the palaeobiogeographical range of Roudairia from Jamaica and Peru northward to California (Textfig. 3). The age range of Roudairia in the eastern Pacific is extended to the latest Maastrichtian (Text-fig. 4).

SYSTEMATIC PALAEONTOLOGY

Abbreviations. The following abbreviations are used with catalogue and locality numbers mentioned in the text: CIT, California Institute of Technology; CSUN, California State University, Northridge; LACMIP, Natural History Museum of Los Angeles County, Invertebrate Paleontology Section; PRI, Paleontological Research Institution; UCLA, University of California, Los Angeles. CIT and UCLA collections are currently at the Natural History Museum of Los Angeles County, Invertebrate Paleontology Section.

Phylum MOLLUSCA Linnaeus, 1758
Class BIVALVIA Linnaeus, 1758
Order VENEROIDA Adams and Adams, 1856
Family ARCTICIDAE Newton, 1891
Genus ROUDAIRIA Munier-Chalmas, 1881

Type species. Roudairia drui Munier-Chalmas, 1881 from the Campanian and Maastrichtian of Tunisia.

Diagnosis. Inflated arcticid bivalves of trigonal to subquadrate outline with a strongly carinate posterior; sculpture of undulating ribs on the flank. Hinge of right valve with three cardinals and four laterals: 1 at the ventral hinge border, anterior to 3a; 3a dorsal to 1; 3b bifid; AI short, subtrigonal; AIII elongate. Hinge of left valve with two cardinals and two laterals; 2b obscurely bifid; 4b elongate, thin; AII chevron-shaped; PII elongate with transverse striations on both sides. Posterior adductor muscle scar bordered anteriorly by a strong myophoric flange.

Discussion. A number of problems with respect to the appropriate generic name for the specimens from Warm Springs Mountain cannot be solved solely on the basis of the Warm Springs Mountain specimens. Of the three generic taxa, Veniella Stoliczka, 1870 (type species Venilia conradi Morton, 1833), Cicatrea Stoliczka, 1870 (type species 'Cyprina' (Cicatrea) cordialis Stoliczka, 1870), and Roudairia Munier-Chalmas, 1881, the specimens from Warm Springs Mountain are least like Veniella. Dartevelle and Freneix (1957) reviewed the status of the generic names Veniella, Cicatrea, and Roudairia. They considered Cicatrea and Roudairia to be synonyms of Veniella because: (1) the separation of Veniella and Roudairia required well-preserved adult hinges; (2) 'Cyprina' forbesiana Stoliczka, 1870, was considered by Vokes (1954) to have a left valve hinge like Roudairia and a right valve hinge resembling Veniella; and (3) some species, such as the Indian Cicatrea cordialis, combine the hinge of Veniella and the external shape and sculpture of Roudairia. Although the types species of Roudairia and Veniella are sufficiently dissimilar to be recognized as representatives of distinct supraspecific taxa, Dartevelle and Freneix (1957) believed that 'Cyprina' forbesiana and Cicatrea cordialis bridge this morphological gap. Vokes (1954) suggested that Veniella is a North American Late Cretaceous group, but he considered Cicatrea cordialis, from India and Madagascar, to be closer to Veniella than to Roudairia. The following discussion outlines what is known of the generic characters of Veniella, Roudairia, and Cicatrea.

The type species of *Veniella*, *V. conradi*, has been illustrated by Vokes (1954). Characters of the genus are discernable from his illustrations and from well-preserved specimens of the type species from the Ripley Formation of Tennessee (Pl. 2, figs 2-4). Exteriorly, the shell has a strong posterior

angulation. Commarginal sculpture anterior to the angulation consists of irregularly developed ridges, the strongest of which are flanged. In the right valve, *V. conradi* has three cardinals, one anterior lateral AII, and two posterior lateral teeth (Pl. 2, fig. 2). In the left valve, *V. conradi* has two cardinals, one elongate to somewhat triangular anterior lateral AII, and one posterior lateral tooth (Pl. 2, fig. 3). *Veniella conradi* lacks an internal myophoric flange bordering the anterior side of the posterior adductor muscle scar. The *Treatise on invertebrate paleontology* illustration of the left valve of *V. conradi* is misleading (Casey 1969, p. N651, text-fig. E129, 6a). Cardinal 2b is never so bifid in mature specimens as depicted (see ontogenetic hinge changes in Vokes (1954, text-figs 1-4, 6-9)) and the adductor muscle scars are discrepant in size and shape. The posterior adductor muscle scar is actually larger and rounder than the semicircular anterior adductor muscle scar.

The nominal type species of Roudairia, R. drui, has been variously synonymized with the prior Opis undatus Conrad, 1852, and Trigonia auressensis Coquand, 1862. But Dartevelle and Freneix (1957, p. 141) rejected the synonymy of R. drui with Roudairia undata and Roudairia auressensis, and listed several characters, including a second posterior carina present in R. undata and finer, more uneven ribbing in R. auressensis, that separate these two species from R. drui. Roudairia drui has been recognized from several horizons and locations (Text-fig. 3), and not all of these specimens are conspecific (Dartevelle and Freneix 1957). This confusion and the poor preservation of some of the material has made generic characters of Roudairia difficult to determine. Exteriorly, R. drui has a carinate posterior angulation accentuated by a strongly raised keel. Roudairia drui is higher than long, and squarely truncated posteriorly. Commarginal ribbing on the anterior portion of the shell is strong and even near the beaks, but becomes more uneven ventrally. The commarginal ribs, although over-steepened, do not give rise to flanges. Vokes (1954) discussed the hinge teeth based on illustrations in Quaas (1902) and Pervinquière (1912). The hinge of R. drui differs from that of V. conradi in having a chevron-shaped anterior lateral AII in the left valve and a pustular anterior lateral AI in the right valve. In contrast, V. conradi has an elongate trigonal AII in the left valve and lacks AI in the right valve. Dartevelle and Freneix (1957) did not indicate whether R. drui has an internal myophoric flange along the anterior side of the posterior adductor muscle scar or not. But Quaas' figure (1902, pl. 24, fig. 22) of a left valve of R. drui indicates that such a flange is present.

Abbass (1962) described several *Roudairia* species from Egypt. Regrettably, he did not refer to Dartevelle and Freneix (1957), nor did he indicate the relationship of his Egyptian taxa to those discussed by Dartevelle and Freneix (1957). In order to settle discrepancies between Abbass (1962) and Dartevelle and Freneix (1957), we would need to examine and compare Abbass' specimens with those described by Dartevelle and Freneix (1957).

The type species of Cicatrea, Cyprina (Cicatrea) cordialis Stoliczka, 1870, has been recognized in various parts of Africa, as well as in India and Madagascar (Dartevelle and Freneix 1957) (Textfig. 3). Discussions of the validity of Cicatrea (Douvillé 1904; Vokes 1954) refer to Stoliczka's figure (1870, pl. 10, fig. 2) of a left valve hinge to define generic characters. Dartevelle and Freneix (1957) did not figure a hinge for this species and did not have any available for study. Although they did not mention an internal myophoric flange, illustrations of specimens identified as C. cordialis by Dartevelle and Freneix (1957) clearly show the presence of an internal flange bounding the anterior side of the posterior adductor muscle scar. Exteriorly, C. cordialis has a high keel along the strong posterior angulation. This keel is particularly pronounced near the beaks. Commarginal sculpture on the anterior portion of the valve is even and roundly ripple-ribbed near the beaks. The commarginal ribs evanesce ventrally. Stoliczka's figure (1870, pl. 10, fig. 2) of the left valve hinge gives the impression of a double exposure. Two hinges appear to be present, one superposed on the other. One hinge is offset higher and to the left of the other hinge. Compared to Veniella and Roudairia, Stoliczka's figure is peculiar in having no upright, flanged posterior end to the nymph. Although broad ligament grooves are indicated, the usual nymph flange is not. Stoliczka (1870) did comment on its absence. If two valves are superposed, one set of the ligament grooves and subumbonal pits would be above and to the left of the other. Cardinal 2b is drawn as a moderately broad triangle and is more like 2b of V. conradi than of R. squiresi and R. peruviana. This broadly triangular cardinal 2b is somewhat surprising as C. cordialis is more elongate with a strong forward

twist to the shell. In *V. conradi*, mature shells of greater elongation and forward twist have a narrower, more elongate 2b, but shorter shells have a more trigonal 2b. The left anterior lateral AII is also peculiar. It is more equantly triangular than that of *V. conradi* and is drawn with the hint of a basal dimple suggesting the possibility of a socket for AI. If *C. cordialis* should be shown to have AI, then its hinge formula would be the same as that of *Roudairia*. Stoliczka (1870, p. 199) said that the base of cardinal 2b is united to the top of AII by a low rib. In *R. squiresi* and *R. peruviana*, a ridge drops from the tip of AII toward the base of 2b, but it encircles the socket for 1 and does not join 2b. Additionally, Stoliczka wrote (1870, p. 199), 'a distinct rib is seen in front of the anterior muscular impression, it has the appearance of an anterior lateral tooth, but has in reality nothing to do with hinge-teeth'. If this figure (Stoliczka, 1870, pl. 10, fig. 2) were drawn from superposed impressions of two shells, the 'distinct rib' would be the anterior margin of the upper, more leftward specimen. *Roudairia squiresi* has a raised anteroventral margin to the anterior adductor muscle scar, but this margin is not sufficiently raised to have the appearance of a tooth.

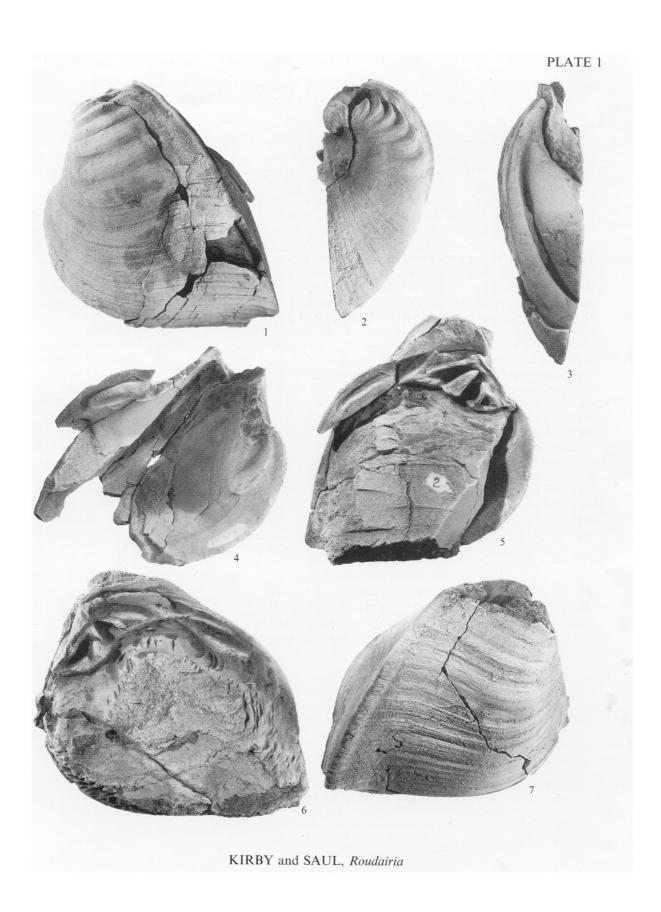

Drawings of C. cordialis credited to Douvillé are in Boule and Thevenin (1906, text-figs 4-6). The drawings are based on rock moulds from Madagascar. Their text-figure 6 of the left hinge greatly resembles Stoliczka's figure 2 (1870, pl. 10) in shape and position of hinge-teeth 2, 4 and AII, except that in Douvillé's text-figure 6, AII is depicted as having a chevron-shape with a well-developed socket for AI in its base. Douvillé's figures (Boule and Thevenin 1906, text-figs 4-6) do not depict any nymph or ligament groove. Their omission may have been caused by incomplete rock moulds.

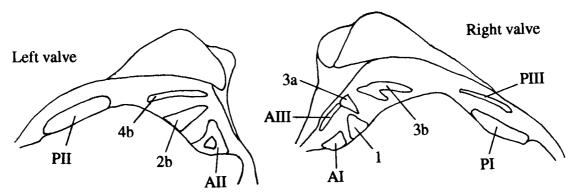

If Stoliczka's left hinge (1870, pl. 10, fig. 2) is drawn accurately, then the hinge of Cicatrea differs from that of Roudairia in the absence of an alate nymph and in having both 2b and AII broadly triangulate. But Douvillé's tooth AII (Boule and Thevenin 1906, text-fig. 6) is more like that of Roudairia and his right valve hinge (Boule and Thevenin 1906, text-fig. 4) shows a well-developed AI similar to that of Roudairia but much more elongate than that seen in R. squiresi or R. peruviana. Differences between illustrations of the Indian C. cordialis of Stoliczka and the Madagascan C. cordialis of Douvillé permit doubt as to whether they are both the same species, especially as the Indian specimens are probably of early Senonian age rather than the Maastrichtian age of the Madagascan specimens. Despite the comments of several palaeontologists (Douvillé 1904; Boule and Thevenin 1906; Rennie 1929; Cox 1952; Vokes 1954; Dartevelle and Freneix 1957), the generic characters of Cicatrea remain ambiguous. Adequate material from the type locality of C. cordialis is necessary to determine how closely Stoliczka's figure (1870, pl. 10, fig. 2) depicts the features these palaeontologists have variously reinterpreted. Based on available illustrations, specimens assigned to C. cordialis by Douvillé (Boule and Thevenin 1906) and Dartevelle and Freneix (1957) are herein referred to Roudairia.

In summary, the present taxonomic status of *Veniella*, *Roudairia*, and *Cicatrea* remains unclear due to the lack of well-preserved specimens of *Cicatrea*. Based on previous work (Boule and Thevenin 1906; Vokes 1954; Dartevelle and Freneix 1957), there are at least two distinct generic groups present. The first group, represented by *Veniella*, is characterized by uneven commarginal

EXPLANATION OF PLATE 1

Figs 1–7. Roudairia squiresi sp. nov. LACMIP locality 14312, Warm Springs Mountain, California; San Francisquito Formation. 1–5, LACMIP 12204, holotype; left valve; 1, exterior showing strong carina on posterior angulation and rounded ripple ribs developed near beak; 2, anterior showing lunule and development of rounded ripple ribs near beak; 3, posterior, shell removed to show mark of internal myophoric flange on rock cast and posterior adductor muscle scar (rough area to right of myophore impression); 4, interior showing myophoric flange and position of adductor muscle scars; 5, hinge, nymph broken, posterior lateral PII, cardinal 4b elongate slender, cardinal 2b elongate trigonal with faint medial groove, anterior lateral AII chevron-shaped. 6–7, LACMIP 12205, paratype; right valve; 6, hinge, nymph nearly complete, anterior laterals AI and AIII, cardinal 1, 3a, and 3b, 3b bifid, posterior laterals PI and PIII; 7, exterior showing strong carina on posterior angulation. TEXT-FIG. 5. Left and right valve hinge areas of Roudairia squiresi with the hinge teeth labelled.

ribbing on the anterior margin that tends to develop flanges, by an angulate but not carinate posterior angulation, by the absence of the anterior-lateral tooth AI, and by the absence of an internal myophoric flange on the anterior side of the posterior adductor muscle scar. The second group, represented by Roudairia, is characterized by even commarginal ribbing which commonly becomes roundly ripple-ribbed on the anterior portion of the shell near the beaks and which evanesces toward the ventral margin in large specimens, by a strongly carinate posterior angulation that is accentuated by a keel, by the anterior-lateral tooth AI, and by an internal myophoric flange bordering the anterior side of the posterior adductor muscle scar. The specimens from Africa and Madagascar previously described as Cicatrea belong in this second group. The Indian specimens described as Cicatrea may also belong in this second group. But until better preserved specimens of Cicatrea from India are available, the relationship of Cicatrea to Veniella and Roudairia will remain unclear.

The specimens from Warm Springs Mountain are distinct from *V. conradi*. They are externally more similar to *R. drui* and *C. cordialis*. Internally, they are more similar to *R. drui*. Previous workers (e.g. Douvillé 1904; Olsson 1934; Vokes 1954) have used various stratagems to avoid replacing the more commonly used and better-based *Roudairia* Munier-Chalmas, 1881, with the enigmatic and ill-defined *Cicatrea* Stoliczka, 1870. Although the similarity of the Warm Springs

Figs 5–8. Roudairia peruviana Olsson. 5–6, PRI 3716, holotype; right valve; Monte Grande, Peru; Monte Grande Formation; 5, exterior with strong carina on posterior angulation and rounded ripple ribs near beak; 6, hinge, lunular margin and anterior portion of hinge damaged, nymph broken. 7, PRI 4825 (exterior figured by Olsson, 1944, pl. 2, fig. 7), hypotype; left valve, interior view, hinge damaged but shows nymph, cardinal teeth 4b and 2b, and chevron-shaped anterior lateral AII, also myophore along posterior muscle scar; Monte Grande, Peru; Monte Grande Formation, specimen not coated. 8, LACMIP 12210, hypotype; right valve, hinge with well- preserved nymph, anterior laterals AI and AIII, cardinals 1, 3a and 3b, 3b widely bifid, posterior laterals PI and PIII; UCLA locality 5261, north of Tortuga, Paita Peninsula, north-western Peru; 'Baculites' beds'.

All figures ×1 and coated with ammonium chloride, except where noted otherwise.

Mountain specimens to *Cicatrea* is unclear, they are in shape, sculpture, internal myophoric flange, and hinge most similar to *Roudairia*. *Roudairia* squiresi is the first species of this group to be found in North America.

Roudairia squiresi sp. nov.

Plate 1, figures 1-7; Plate 2, figure 1

1991 Roudairia peruviana? Olsson, 1934; Kirby, p. 133, pl. 3, figs 6, 7.

Derivation of name. The species is named for Richard L. Squires whose work on Eocene molluscs of the eastern Pacific has greatly improved our understanding of Tethyan migrations into California.

Holotype. LACMIP 12204; San Francisquito Formation (uppermost Maastrichtian); LACMIP locality 14312, Warm Springs Mountain, Los Angeles County, southern California, USA.

Paratypes. Five specimens: LACMIP 12205–12206 from LACMIP locality 14312; LACMIP 12207–12208 from UCLA locality 1591; LACMIP 12209 from LACMIP locality 14316; all from San Francisquito Formation (uppermost Maastrichtian); Warm Springs Mountain, Los Angeles County, southern California, USA.

Diagnosis. A large Roudairia of nearly equant proportions, but with the beaks curled well forward, sculptured near the beaks by ten to fourteen undulatory commarginal ribs that evanesce ventrally, with a strong posterior carina along the posterior angulation. Cardinals 3b and 2b relatively narrow and posteriorly directed (Text-fig. 5).

Description. Shell large, higher than long, subquadrate, inflated, thick; beaks strongly enrolled, strongly prosogyrous; lunular margin nearly straight; anterior end broadly rounded; ventral border nearly straight with a slight sulcus to the anterior of the posterior carination and a little rostrate at the carination; posterior border nearly straight, rounding into dorsal border; lunule large, depressed, bounded by an inscribed line; no escutcheon; posterior carination high, alate near the beaks, abruptly carinate at the ventral border; paralleled anteriorly by a shallow sulcus. External sculpture of about ten to fourteen strong, broad, undulatory, commarginal ribs on beak, diminishing in height ventrally, extending from anterior slope break to sulcus anterior to carina. Entire surface marked by uneven commarginal growth lines.

Ligament groove deep, arched behind strong alate nymphs. Hinge of right valve with short, strong 1 at the hinge border anterior to 3a (Text-fig. 5); short, ventrally directed 3a; strong, bifid, posteriorly directed 3b; anterior laterals AI and AIII low; AI short subtrigonal; AIII elongate, paralleling the valve margin; socket for AII chevron-shaped; PI and PIII elongate with PI longer; PIII paralleling the valve margin; socket for PII deep. Hinge of left valve with 2b elongate, narrowly trigonal, obscurely bifid, posteroventrally directed; 4b elongate, thin, posteriorly directed, dorsal to bifid socket for 3b; anterior lateral AII chevron-shaped around shallow socket for AI, anterior to very deep socket for 1; PII elongate, strong, with transverse striations on both sides. Adductor muscle scars strongly marked, anterior impressed and bounded by raised rim, posterior impressed and bounded along anterior side by a strongly raised myophoric flange beginning near the beak and extending to ventral edge of muscle scar.

Measurements. LACMIP 12204 height 70·0 mm, length 70·0 mm, inflation 35·0 mm; LACMIP 12205 height 69·0 mm, length 66·5 mm incomplete, inflation 29·6 mm.

Remarks. Roudairia squiresi is similar to Roudairia peruviana Olsson, 1934, and to Roudairia jamaicensis Trechmann, 1927. These Roudairia are large and very trigoniiform, have strong, undulatory, commarginal sculpture on the flanks near the beaks that evanesce well before the ventral margin, have a strong posterior carina along the posterior angulation, and have an inscribed lunule. Internally, they have a strong myophoric flange bordering the anterior side of the posterior adductor muscle scar. The anterior left lateral AII is strongly hooked and forms a chevron, the right anterior lateral AI is present, and the socket for AII is chevron-shaped (Text-fig. 5).

Roudairia squiresi differs from R. peruviana (Pl. 2, figs 5-8) from the Maastrichtian of Peru in being less upright, having the beaks curled more forward, having a shallower sulcus anterior to the carina, and having commarginal ribs that are greater in number, narrower, and closer together. Roudairia squiresi contrasts with R. jamaicensis from the Campanian of Jamaica in being less elongate and having coarser and more pronounced commarginal ribbing. Trechmann figured a mature left valve and an immature right valve of R. jamaicensis (1927, pl. 2, figs 1-2). The immature right valve is more elongate than similar sized specimens of R. squiresi and has finer and less pronounced ribbing. Although Trechmann's figure (1927, pl. 2, fig. 1) of a mature left valve appears to be relatively higher, his measurements indicate that mature specimens are also more elongate than high, whereas in R. squiresi, height and length are more nearly equal.

Veniella conradi (Morton 1833) is less trigoniiform. It has distant, flanged commarginal sculpture and a strong posterior angulation that does not bear a raised carina like that of R. squiresi. Veniella conradi lacks the internal posterior myophore, its lunule is not inscribed, anterior lateral AII is elongate, trigonal, and the right anterior lateral AI is not present (Pl. 2, figs 2-4).

Vokes (1954, text-figs 6–9) illustrated the changes in the left cardinal 2b of *V. conradi* from juvenile inverted V-shaped to compressed trigonal, obscurely bifid adult. The obscurely bifid character of 2b in *R. squiresi* suggests that it too results from the compression of a widely bifid, inverted V-shaped, juvenile tooth.

The ligament of R. squiresi is enlarged below the beak similar to many large venerids (e.g. Dosinia ponderosa (Gray 1838)). A similar subumbonal ligamental pit may be the structure that caused Stoliczka (1870) to describe the ligament of Cyprina (Cicatrea) cordialis as lying in a double groove. In R. squiresi, this elongate pit encroaches on the anterior end of the nymph, notching it just behind the beak, and creating exteriorly a pattern of shell and notches similar to that seen in Stoliczka's figure 1b (1870, pl. 10).

Only a few specimens of *R. squiresi* have been found, including eight nearly complete large valves from Warm Springs Mountain. A fragment of a left valve from UCLA locality 6525 on Dip Creek, San Luis Obispo County, central California, consists only of the anterior part of the hinge, the lunule, and a suggestion of undulatory commarginal ribbing. The fragment is too incomplete to identify with certainty, but is probably *R. squiresi*.

Stratigraphical range. Uppermost Maastrichtian.

Geographical distribution. Warm Springs Mountain, Los Angeles County, and Dip Creek, south shore of Lake Nacimiento, San Luis Obispo County, central California, USA.

Acknowledgements. We thank: P. Hoover of the Paleontological Research Institute for the loan of A. A. Olsson's type and figured specimens from Peru; Sean Connell and R. L. Squires of the California State University, Northridge, who collected some of the specimens at Warm Springs Mountain; M. McIntyre and M. Wickman of the Angeles National Forest for allowing access to Warm Springs Mountain and granting permission to collect specimens; and Hayes Graphics for their computer and copy support. Photographs of the specimens were taken by J. De Leon, Natural History Museum of Los Angeles County. Discussions with G. Kennedy and E. Wilson were fruitful. This paper has benefited from a review by R. . Squires and two anonymous reviewers.
